ANSWER 1 OF 4 CAPLUS COPYRIGHT 2004 ACS on STN DUPLICATE 1

L19 AN

2004:372937 CAPLUS

AB A process for producing 1,3-propanediol comprises: (a) forming an aqueous solution of 3-hydroxypropanal; (b) hydrogenating the 3-hydroxypropanal to form a first crude 1,3-propanediol mixture containing 1,3-propanediol, water, and a cyclic acetal (I); (c) distilling the first crude 1,3-propanediol mixture to remove water and low-boiling impurities and form a second crude 1,3-propanediol mixture; (d) contacting the second crude 1,3-propanediol mixture with a solid acid purifier (e.g., Amberlyst A15) at 50-250° to convert the I to more volatile cyclic acetals; and (e) separating the more volatile cyclic acetals from the 1,3-propanediol by distillation or gas stripping.

Communicating local information, such as a user interface language, between a host application and a software component. In response to a user's request, the host application invokes the software component to perform a task addressing the user's request, such as generating user interface message. In order to determine the appropriate language for the user interface message, the software component queries the host application to identify the user and to return the user interface language requirements for the user. In the case where the host application is an end-user application, the host returns the current user interface language as the user interface language requirement. When the host application is a server application using a multi-threaded environment, the host application returns the user interface language of the currently running thread at the time of the query. If the host application is not an end-user application or does not use a multi-threaded architecture, the software component provides contextual information in a parameter of the query to aid the host application in determining the user interface language requirements. In the event that the software component does not receive user interface requirements from the host application, the software component follows a priority scheme to determine the user interface language.     WO 1999-US19980
     A two-stage process for producing 1,3-propanediol comprises first
AB
     hydrogenating 3-hydroxypropanal at 30-80° in the presence of an
     oxide-supported metal hydrogenation catalyst and the resulting reaction
     solution (containing the 1,3-propanediol acetal of 3-hydroxypropanal, which
     acetal boils at a similar temperature to 1,3-propanediol) is then hydrogenated
     at 80-180° to a 3-hydroxypropanal conversion of substantially 100%
     in the presence of an activated carbon-supported metal hydrogenation
     catalyst.

     The hydrogenation of 3-hydroxypropanal (HPA) to 1,3-propanediol (PD) over
AB
     Ni/SiO2/Al2O3 catalyst powder was carried out at 318-353 K and 2.60-5.15
     MPa in a batchwise-operated stirred autoclave. A kinetic model which can
     well describe the reactions of this process was developed. The model
     parameters were estimated by the maximum likelihood function of the
concentration of HPA
     and PD according to concentration-time profiles measured at different temps.
and
     pressures. To obtain high selectivity of PD the reaction temperature should be
     lower than 333 K.

     (Dialkoxymethyl)lithium reagents, (RO)2CHLi, can be generated simply and
AΒ
     efficiently and employed as synthetically useful one-carbon nucleophiles.
     Reductive lithiation of phenylthio-substituted precursors, (RO)2CHSPh, at
     -95° or transmetalation of tri-n-butylstannyl compds.,
     (RO) 2CHSnBu3, at -110 to -111° afforded the acyclic species
     (MeO) 2CHLi and (EtO) 2CHLi. The cyclic reagents 2-lithio-1,3-dioxolane and
     2-lithio-1,3-dioxane (I), were similarly prepared at -78° by
     reductive lithiation or transmetalation. Reactions of
     (dialkoxymethyl) lithiums with electrophiles, including aldehydes, ketones,
     2-cyclohexen-1-one (1,2- or 1,4-addition as desired), di-Me sulfate, primary
```

alkyl bromides, epoxides, oxetane, and Bu3SnCl, afforded structurally diverse, functionalized acetals. In these expts., which emphasized transformations of I yields of products generally exceeded 90%. The thermal stability of each reagent was investigated at several temps. acyclic compds. decompose rapidly even at -95°, whereas lithiodioxolane and -dioxane derivs. are relatively stable at -78 and -45°, resp. These striking differences in solution lifetimes can be rationalized in terms of alternative decomposition pathways and steric and stereoelectronic factors. The primary products of thermal decomposition of I can be ascribed to formation of a reactive carbene or carbenoid via α -elimination. Equilibration expts. established that (dialkoxymethyl)lithium I is more stable thermodynamically than the α-monoalkoxy species [(benzyloxy)methyl]lithium, in accord with previous ab initio calcns. **5465-07-6P**, 1,3-Dioxane-2-ethanol RL: SPN (Synthetic preparation); PREP (Preparation) (preparation of) 5465-07-6 CAPLUS 1,3-Dioxane-2-ethanol (9CI) (CA INDEX NAME) ${

β-Cyclopropylidenic alcs. were prepared in 4 steps from cyclopropylidenetriphenylphosphorane (I; Z = PPh3) (II). E.g., II underwent Wittig reaction with MeCOCHMeCHZ1 [Z1 = O(CH2)30] (NaH/MeOCH2CH2OMe, room temperature then 68-70°, 68 h) followed by transacetalization and hydrolysis to give the aldehyde I (Z = :CMeCHMeCHO), which was reduced (LiAlH4) to give the primary alc. I (Z =

```
:CMeCHMeCH2OH). Similar reaction of II with MeCOCHMeCMeZ2 (Z2 = OCH2CH2O)
      gave the secondary alc. I [Z = :CMe(CHMe)2OH] via the LiAlH4 reduction of I (Z = :CMeCHMeCOMe) (III). Methylation (MeLi) of III gave I (Z =
      :CMeCHMeCMe2OH).

AB An improvement upon the process for the production of 1,3-propanediol (PDO) is described where an aqueous solution of 3-hydroxypropanal (HPA) is formed, and the

HPA is subjected to hydrogenation to produce a crude PDO mixture comprising PDO, water, an acetal (I), and high- and low-volatility materials, where the crude PDO mixture is dried to produce a first overhead stream comprising water and some high volatility materials and a dried crude PDO mixture as a first distillate bottoms stream comprising PDO, I, and low-volatility materials, and where the dried crude PDO mixture is distilled to produce a second overhead stream comprising some high-volatility materials, a middle stream comprising PDO and I, and a second distillate bottoms stream comprising PDO and low-volatility materials. The improvement in this process comprises treating the crude PDO mixture and/or the dried crude PDO mixture and/or the PDO product with an acidic zeolite, an acidic cation exchange resin, or a soluble acid to convert the I into more volatile materials which can be easily separated from PDO by distn; a process flow diagram is presented.
